## Ignoring long-term trends due to distracting long-term trends

### What The Science Says:

Soares looks at short-term trends which are swamped by natural variations. Increasing CO<sub>2</sub> causes a gradual long-term warming trend which is smaller than the short-term variations. The long-term correlation between CO<sub>2</sub> and temperature is well established.

### Climate Myth: Soares finds lack of correlation between CO<sub>2</sub> and temperature

"The comparison of temperature changes and CO<sub>2</sub> changes in the atmosphere is made for a large diversity of conditions, with the same data used to model climate changes. Correlation of historical series of data is the main approach. CO<sub>2</sub> changes are closely related to temperature. Warmer seasons or triennial phases are followed by an atmosphere that is rich in CO<sub>2</sub>, reflecting the gas solving or exsolving from water, and not photosynthesis activity. Interannual correlations between the variables are good. A weak dominance of temperature changes precedence, relative to CO<sub>2</sub> changes, indicate that the main effect is the CO<sub>2</sub> increase in the atmosphere due to temperature rising. Decreasing temperature is not followed by CO<sub>2</sub> decrease, which indicates a different route for the CO<sub>2</sub> capture by the oceans, not by gas re-absorption. Monthly changes have no correspondence as would be expected if the warming was an important absorption-radiation effect of the CO<sub>2</sub> increase. The anthropogenic wasting of fossil fuel CO<sub>2</sub> to the atmosphere shows no relation with the temperature changes even in an annual basis. The absence of immediate relation between CO<sub>2</sub> and temperature is evidence that rising its mix ratio in the atmosphere will not imply more absorption and time residence of energy over the Earth surface." ([Paulo Soares](#))

A recent paper in an obscure journal ([Soares, 2010](#)) used correlations between temperatures and CO<sub>2</sub> concentrations to conclude that;

"The absence of immediate relation between CO<sub>2</sub> and temperature is evidence that rising its mix ratio in the atmosphere will not imply more absorption and time residence of energy over the Earth surface. This is explained because band absorption is nearly all done with historic CO<sub>2</sub> values."

Soares looks at correlations between change in CO<sub>2</sub> and change in temperature for a month to a few years. He doesn't find a correlation between short term CO<sub>2</sub> changes and temperature changes in the following months. His Figure 8 shows the change in temperature or CO<sub>2</sub> from one year to the next.

**Figure 8. Cross plot between the annual increase of CO<sub>2</sub> in the atmosphere and average temperature change by latitude bands: Mid NH and Mid SH, latitudes 20 to 40, north and south hemispheres; T\_NH and T\_SH, 0 to 20 north and south. (Data from CDIAC/NOAA; [17] and NASA [15,18].**

Do we live in Soares' world where CO<sub>2</sub> isn't causing warming, or in the world of mainstream physics where [theory](#) and [measurements](#) show increased CO<sub>2</sub> heating? What does mainstream physics expect to see in the above graph?

Firstly it expects atmospheric temperatures to change regularly: natural cycles like El Nino transfer heat from the oceans and can change atmospheric temperature by up to 0.4 °C in a year causing the big vertical spread.

The graph below is based on [Meehl et al. 2004](#) and shows a climate model estimate of how much global warming was expected from greenhouse gases for the past century: always less than 0.02 °C/year - so small that the noise effectively hides the incline if you only look at year to year *changes*. Fortunately, [very simple statistical techniques work around this](#).

Some rough calculations using the NASA global data shows that to detect the expected CO<sub>2</sub> global warming for the past 40 years at 95% confidence would require about 160 years of measurements - and hundreds more measurements to detect the CO<sub>2</sub> signal when it is smaller.

We have some more expectations for the graph: low CO<sub>2</sub> emissions should mean slow warming and vice versa. On the left of the graph we expect average warming of under 0.01 °C/yr and on the right hand side we expect just under 0.02 °C/yr. So if you plot a slope you expect it to be positive – going from 0.01 on the left up to 0.02 on the right but practically impossible to find amongst so much noise (although Soares does plot it).

The next trick is to implicitly assume that nothing else shows a warming or cooling pattern: but we know that there is. From the [1940s to the 1970s we pumped enough reflective aerosols into the atmosphere to temporarily halt global warming](#) by 'global dimming' ([Ramanathan et al, 2001](#)).

This is like putting a pan of water over a lit gas stove and then dropping in an icepack big enough to cool the water. Soares would say the cooling shows that burning gas can't heat water, but mainstream science says that a big pack of ice temporarily masks the heating and that burning gas does, in fact, make water warmer than it would otherwise be. Importantly, you can account for the ice and determine whether the heat is on and other scientists would do this.

Soares' method is like searching for a needle in a huge haystack by picking a handful of hay rather than using a magnet. You almost certainly wouldn't find the needle even if it was there, so to claim you've disproved its existence when [other scientists have found it with their magnets](#) is simply stunning.
